PREFACE

THE mathematical treatment of the principles of mathematics, which is
the subject of the present work, has arisen from the conjunction of two
different studies, both in the main very modern. On the one hand we have
the work of analysts and geometers, in the way of formulating and systematizing
their axioms, and the work of Cantor and others on such matters as the theory
of aggregates. On the other hand we have symbolic logic, which, after a
necessary period of growth, has now, thanks to Peano and his followers,
acquired the technical adaptability and the logical comprehensiveness that are
essential to a mathematical instrument for dealing with what have hitherto
been the beginnings of mathematics. From the combination of these two
studies two results emerge, namely (1) that what were formerly taken, tacitly
or explicitly, as axioms, are either unnecessary or demonstrable; (2) that the
same methods by which supposed axioms are demonstrated will give valuable
results in regions, such as infinite number, which had formerly been regarded
as inaccessible to human knowledge. Hence the scope of mathematics is
enlarged both by the addition of new subjects and by a backward extension
into provinces hitherto abandoned to philosophy.

The present work was originally intended by us to be comprised in
a second volume of The Principles of Mathematics. With that object in
view, the writing of it was begun in 1900. But as we advanced, it became
increasingly evident that the subject is a very much larger one than we had
supposed; moreover on many fundamental questions which had been left
obscure and doubtful in the former work, we have now arrived at what we
believe to be satisfactory solutions. It therefore became necessary to make
our book independent of The Principles of Mathematics. We have, however,
avoided both controversy and general philosophy, and made our statements
dogmatic in form. The justification for this is that the chief reason in favour
of any theory on the principles of mathematics must always be inductive,
i.e. it must lie in the fact that the theory in question enables us to deduce
ordinary mathematics. In mathematics, the greatest degree of self-evidence
is usually not to be found quite at the beginning, but at some later point;
hence the early deductions, until they reach this point, give reasons rather
for believing the premises because true consequences follow from them, than
for believing the consequences because they follow from the premises.

In constructing a deductive system such as that contained in the present
work, there are two opposite tasks which have to be concurrently performed.
On the one hand, we have to analyse existing mathematics, with a view
to discovering what premises are employed, whether these premises are
mutually consistent, and whether they are capable of reduction to more
fundamental premises. On the other hand, when we have decided upon
our premises, we have to build up again as much as may seem necessary
of the data previously analysed, and as many other consequences of our
premises as are of sufficient general interest to deserve statement. The
preliminary labour of analysis does not appear in the final presentation,
which merely sets forth the outcome of the analysis in certain undefined
ideas and undemonstrated propositions. It is not claimed that the analysis
could not have been carried farther: we have no reason to suppose that it is
impossible to find simpler ideas and axioms by means of which those with
which we start could be defined and demonstrated. All that is affirmed is
that the ideas and axioms with which we start are sufficient, not that they
are necessary.

In making deductions from our premises, we have considered it essential
to carry them up to the point where we have proved as much as is true in
whatever would ordinarily be taken for granted. But we have not thought
it desirable to limit ourselves too strictly to this task. It is customary to
consider only particular cases, even when, with our apparatus, it is just as
easy to deal with the general case. For example, cardinal arithmetic is
usually conceived in connection with finite numbers, but its general laws
hold equally for infinite numbers, and are most easily proved without any
mention of the distinction between finite and infinite. Again, many of the
properties commonly associated with series hold of arrangements which are
not strictly serial, but have only some of the distinguishing properties of
serial arrangements. In such cases, it is a defect in logical style to prove
for a particular class of arrangements what might just as well have been
proved more generally. An analogous process of generalisation is involved,
to a greater or less degree, in all our work. We have sought always the
most general reasonably simple hypothesis from which any given conclusion
could be reached. For this reason, especially in the later parts of the book,
the importance of a proposition usually lies in its hypothesis. The conclusion
will often be something which, in a certain class of cases, is familiar, but the
hypothesis will, whenever possible, be wide enough to admit many cases
besides those in which the conclusion is familiar.

We have found it necessary to give very full proofs, because otherwise
it is scarcely possible to see what hypotheses are really required, or whether
our results follow from our explicit premises. (It must be remembered that we are not affirming merely that such and such propositions are true, but also that the axioms stated by us are sufficient to prove them.) At the same time, though full proofs are necessary for the avoidance of errors, and for convincing those who may feel doubtful as to our correctness, yet the proofs of propositions may usually be omitted by a reader who is not specially interested in that part of the subject concerned, and who feels no doubt of our substantial accuracy on the matter in hand. The reader who is specially interested in some particular portion of the book will probably find it sufficient, as regards earlier portions, to read the summaries of previous parts, sections, and numbers, since these give explanations of the ideas involved and statements of the principal propositions proved. The proofs in Part I, Section A, however, are necessary, since in the course of them the manner of stating proofs is explained. The proofs of the earliest propositions are given without the omission of any step, but as the work proceeds the proofs are gradually compressed, retaining however sufficient detail to enable the reader by the help of the references to reconstruct proofs in which no step is omitted.

The order adopted is to some extent optional. For example, we have treated cardinal arithmetic and relation-arithmetic before series, but we might have treated series first. To a great extent, however, the order is determined by logical necessities.

A very large part of the labour involved in writing the present work has been expended on the contradictions and paradoxes which have infected logic and the theory of aggregates. We have examined a great number of hypotheses for dealing with these contradictions; many such hypotheses have been advanced by others, and about as many have been invented by ourselves. Sometimes it has cost us several months' work to convince ourselves that a hypothesis was untenable. In the course of such a prolonged study, we have been led, as was to be expected, to modify our views from time to time; but it gradually became evident to us that some form of the doctrine of types must be adopted if the contradictions were to be avoided. The particular form of the doctrine of types advocated in the present work is not logically indispensable, and there are various other forms equally compatible with the truth of our deductions. We have particularized, both because the form of the doctrine which we advocate appears to us the most probable, and because it was necessary to give at least one perfectly definite theory which avoids the contradictions. But hardly anything in our book would be changed by the adoption of a different form of the doctrine of types. In fact, we may go farther, and say that, supposing some other way of avoiding the contradictions to exist, not very much of our book, except what explicitly deals with types, is dependent upon the adoption of the doctrine of types in any form, so soon as it has been shown (as we claim
that we have shown) that it is possible to construct a mathematical logic which does not lead to contradictions. It should be observed that the whole effect of the doctrine of types is negative: it forbids certain inferences which would otherwise be valid, but does not permit any which would otherwise be invalid. Hence we may reasonably expect that the inferences which the doctrine of types permits would remain valid even if the doctrine should be found to be invalid.

Our logical system is wholly contained in the numbered propositions, which are independent of the Introduction and the Summaries. The Introduction and the Summaries are wholly explanatory, and form no part of the chain of deductions. The explanation of the hierarchy of types in the Introduction differs slightly from that given in §12 of the body of the work. The later explanation is stricter and is that which is assumed throughout the rest of the book.

The symbolic form of the work has been forced upon us by necessity: without its help we should have been unable to perform the requisite reasoning. It has been developed as the result of actual practice, and is not an excrescence introduced for the mere purpose of exposition. The general method which guides our handling of logical symbols is due to Peano. His great merit consists not so much in his definite logical discoveries nor in the details of his notations (excellent as both are), as in the fact that he first showed how symbolic logic was to be freed from its undue obsession with the forms of ordinary algebra, and thereby made it a suitable instrument for research. Guided by our study of his methods, we have used great freedom in constructing, or reconstructing, a symbolism which shall be adequate to deal with all parts of the subject. No symbol has been introduced except on the ground of its practical utility for the immediate purposes of our reasoning.

A certain number of forward references will be found in the notes and explanations. Although we have taken every reasonable precaution to secure the accuracy of these forward references, we cannot of course guarantee their accuracy with the same confidence as is possible in the case of backward references.

Detailed acknowledgments of obligations to previous writers have not very often been possible, as we have had to transform whatever we have borrowed, in order to adapt it to our system and our notation. Our chief obligations will be obvious to every reader who is familiar with the literature of the subject. In the matter of notation, we have as far as possible followed Peano, supplementing his notation, when necessary, by that of Frogo or by that of Schröder. A great deal of the symbolism, however, has had to be new, not so much through dissatisfaction with the symbolism of others, as through the fact that we deal with ideas not previously symbolised. In all
questions of logical analysis, our chief debt is to Frege. Where we differ from him, it is largely because the contradictions showed that he, in common with all other logicians ancient and modern, had allowed some error to creep into his premises; but apart from the contradictions, it would have been almost impossible to detect this error. In Arithmetic and the theory of series, our whole work is based on that of Georg Cantor. In Geometry we have had continually before us the writings of v. Staudt, Pasch, Peano, Pieri, and Veblen.

We have derived assistance at various stages from the criticisms of friends, notably Mr G. G. Berry of the Bodleian Library and Mr R. G. Hawtrey.

We have to thank the Council of the Royal Society for a grant towards the expenses of printing of £200 from the Government Publication Fund, and also the Syndics of the University Press who have liberally undertaken the greater portion of the expense incurred in the production of the work. The technical excellence, in all departments, of the University Press, and the zeal and courtesy of its officials, have materially lightened the task of proof-correction.

The second volume is already in the press, and both it and the third will appear as soon as the printing can be completed.
